Introduction

_		
		2
	On the ConTEXt mailing list, occasionally a user asks if we can post a complete	3
	document with the associated style. One reason for not honouring this request is	4
	that we want users to cook up their own styles. Besides that, there are a couple	
	of styles in the regular ConT _F Xt distribution.	6
	When browsing through this document, a ConTEXt user may wonder what style	7
	was used to achieve its look and feel. We hope that while reading the text and	
	playing with the examples, the reader will accomplish the skills to define more	
	than just simple layouts.	10
	This document is not easy reading. Occasionally we spend some time explaining	
	features not described in other manuals. The design of this document is to a	
_		
_	large extent determined by its purpose, and as a result not always functional	
-	For instance, we typeset on a grid which doesn't look too good. Also the order	
-	of presenting features, tips and tricks is kind of random and unstructured. The	
-	idea is that the visual effects will draw you to the right trick. Also, if you really	
_	want to benefit from these features, there is no way but to read the whole story	
	In spite of all its shortcomings, I hope that you enjoy reading this (yet unfinished)	
_	manual. Keep in mind that this manual is far from finished.	19

	The grid snapper in MkIV is quite different from the one in MkII. For not too	_ 3
	complex layouts the old grid snapper was quite ok, but the new one should be a	
	oit more robust. In the old situation the running text was assumed to fit on the	_ 5
_	grid and the normal baseline skip should do the job in combination with the grid	6
_	aware spacing features and placement mechanisms like tables and figures.	_ 7
_	Snapping on a fixed grid is sort of counter intuitive in $T_{\hbox{\footnotesize E}}X$ because it has an a	8
	to support it. Of course when complex layouts are involved in a later stage of	
	document preparation the grid is often abandoned. This manual uses the grid but	
	I personally never use the grid. There are better ways to make your document	
	ook good and often a grid snapped document doesn't look that great anyway,	
	because all elements should somehow fit in multiples of the line height.	14
	The MkIV snapper does more analysis and therefore can compensate for the more	
	nasty cases. Of course it can still fail but we hope to fix those cases when we run into them. Grids are controlled by keywords or a combination of them.	
	mico meni. Grido are controlled by keywords of a combination of meni.	17 18

A rather common way to draw attention to a passage, is to add a background. In this chapter we will therefore discuss how to enhance your document with those colorful areas that either or not follow the shape of your paragraph. Be warned: this chapter has so many backgrounds that you might start to dislike them. In the previous paragraph we demonstrated two important features of the background handler: you can nest backgrounds and backgrounds can be tight or wide. Features like this will often be used in combination with others, like spe- 8 cial section headers. The raw coding of the previous paragraph is therefore not representative. \starttextbackground[intro] A rather common way to draw attention to a passage, is to add a background. In this chapter we will therefore discuss how to enhance 14 document with \starttextbackground [subintro] those colorful areas that either or not follow the shape of your paragraph. \stoptextbackground\ Be warned: this chapter has so many backgrounds that you might start to dislike them. \stoptextbackground The outer background commands is defined as follows: \definetextbackground [intro] [backgroundcolor=infogray, backgroundoffset=.25cm, frame=off. location=paragraph, color=red Here, the paragraph option ensures that the background covers the width of the body text. The inner background is defined in a similar way, but this time we choose text location. \definetextbackground [subintro] [backgroundcolor=textgray, backgroundoffset=0pt, frame=off, location=text, color=bluel In this document we use protruding characters (hanging punctuation) so we've 46 chosen a rather large offset, one that also matches the rest of the page design. Those who are familiar with the way TEX works will probably see what problems 48 can occur with backgrounds like this. What happens for instance when we cross page boundaries, and how will more complicated paragraph shapes be handled? The current implementation tries to handle page breaks and paragraph shapes as good as possible. This works well in normal one–column mode as well as in columns. In this example, the paragraph shape is determined by the graphic placed left of the text. This feature is implemented using the \hangindent and \hangafter primitives, which means that we need to keep track of their state. In addition, we need to handle the indentation directives \leftskip, \rightskip and \parindent. Be-Figure 3.1 cause backgrounds end up in a different background overlay, nesting 11 them is no problem, and it is even possible to move them to the front_12 and back, as we will demonstrate later on. While the mechanism discussed here 13 will always be improved when we find border cases, the fundaments it is built 14 upon are quite stable. \placefigure[left]{}{\externalfigure[detcow][width=2cm]} \starttextbackground [A] In this example, the paragraph shape is determined by the graphic placed left of the text. \starttextbackground [B] This feature is implemented using the \type {\hangindent} and \type {\hangafter} primitives, which means that we need to keep track of their state. In addition, we need to handle the indentation directives \type {\leftskip}, \type {\rightskip} and \type {\parindent}. \stoptextbackground\ Because backgrounds end up in a different background overlay, nesting them is no problem, and it is even possible to move them to the and back, as we will demonstrate later on. While the mechanism discussed here will always be improved when we find border cases, the fundaments it is built upon are quite stable. \stoptextbackground The backgrounds were defined as: \definetextbackground [A] [backgroundcolor=infogray] 45 \definetextbackground [B] [backgroundcolor=textgray] 47 \setuptextbackground

and end rightmost. In this case inserts (like floats) have to be dealt with after the shape has been calculated. A background can be in-line (the text location variant) in which case we need to follow the paragraph shape, if set. In that case we have a mix of calculating the background shape and afterwards compensating for inserts. A third case is tabulation and tables where we have dedicated regions to deal with. When these float we need to make sure that the backgrounds are adapted to the where they end up. Yet another case is in columns, where we hape multiple regions to deal with. As mentioned, floats need special treatment and they can be part of the page flow but also end up left or right of the text (either or not shifted) but also 15 in the margins, edges, back- or cutspace. Their placement influences the way backgrounds are calculated so additional information needs to travel with them. We distinguish between a paragraph background, which runs between the left and right skip areas and a text background which follows a shape. In figure 3.5 we see a test case with several such shapes. In the case of side floats the following cases occur. Of course multiple such cases can follow each order so in practice we have to deal with an accumulation. As often in TFX coming up with a solution is not a the problem but interference is. You can cook up a solution for one case that fails in another. Backgrounds fall into this category, as do side floats. In the next pages we will demonstrate a few cases. In practice you can probably always come up with something that works out well, but in an automated workflow (like unattended xml to pdf conversion) you can best play safe. We show some examples on the next pages. 47

Regular (page flow) floats are a different story. Here we have the problem that 38
a float might be postpones because there is no room on the current page and
they are moved forward (which is why they're called float). Again we show some 40
examples.
One problem introduced by the internet is that one can view music online. Well
it's actually not really a problem as it is fun to do, but it does interfere with
development of code: one can enter distraction mode quite easily.
                                                                            46
                                                                           47

Because of its look and feel, a math formula can look too widely spaced when put on a grid. There are a few ways to control this. First of all, the default grid option bound to math is already more tolerant. But you can control it locally too. Take the following formula:

$$a = b^c$$

This has been entered as:

\startformula a = b^c

\stopformula

and because it is just a line of math it comes out as expected. The next code

\startformula

a = \frac {a} {b}
\stopformula

produces a higher line:

$$a = \frac{a}{b}$$

as does:

\startformula

a = \frac {\frac {b} {c}} {\frac {d} {e}}

\stopformula

$$a = \frac{\frac{b}{c}}{\frac{d}{e}}$$

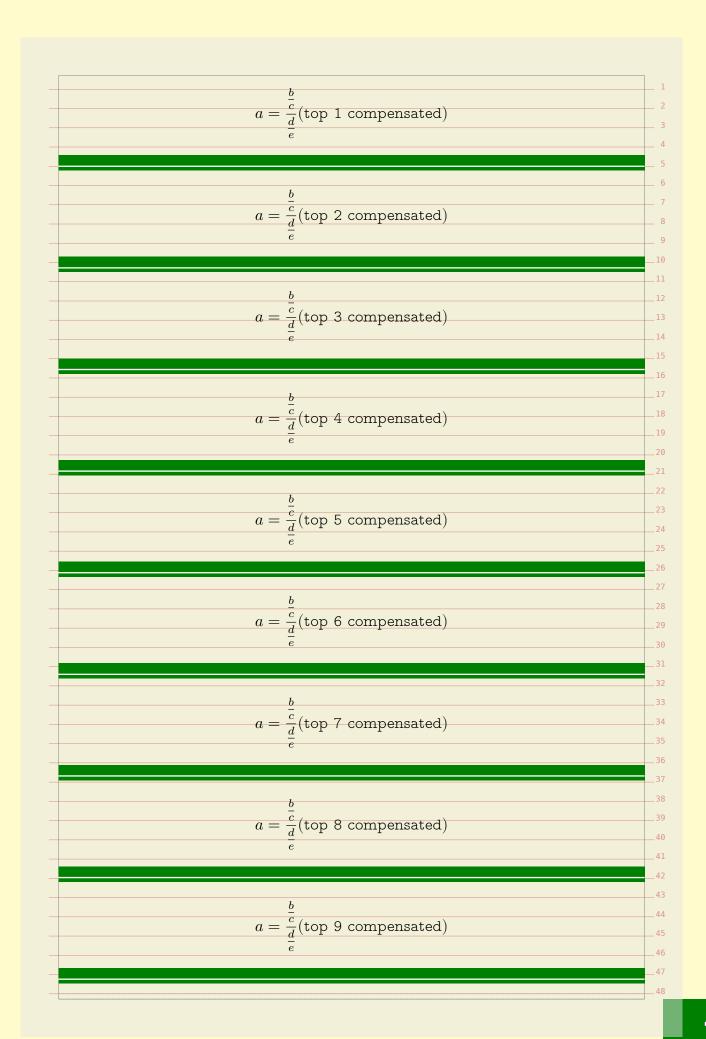

45

47

We will now demonstrate three ways to compensate fo rexcessive spacing. The first variant just sets a grid parameter: \startformula[grid=math:-halfline] a = \frac {\frac {b} {c}} {\frac {d} {e}} \stopformula You can also pass this as an option. Only a few such grid related options are defined: halfline, line, -halfline and -grid. \startformula[-halfline] a = \frac {\frac {b} {c}} {\frac {d} {e}} \stopformula If you need to compensate frequently you can consider defining an instance: \defineformula[tight][grid=math:-halfline] \starttightformula a = \frac {\frac {b} {c}} {\frac {d} {e}} \stoptightformula The result can be somewhat unexpected at the top and bottom of a page. When we subtract half a line from the height we can end up above the text area. This

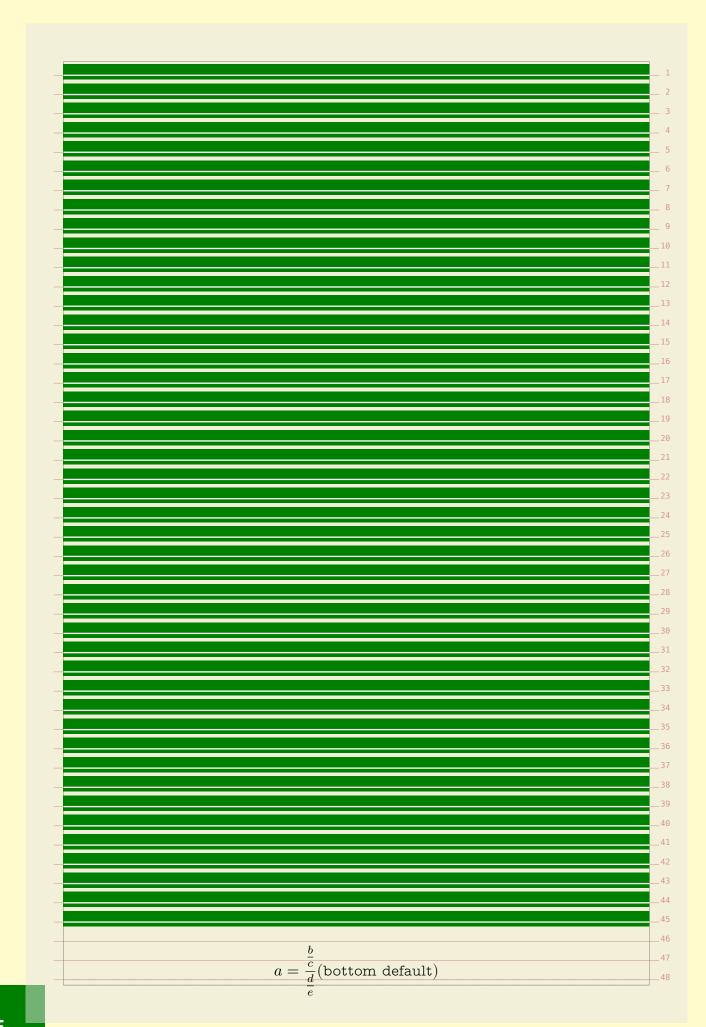

as -	t directive comes in. So, the compensations are actually defined
nath	maxdepth:1.05,maxheight:1.05,strut
math:line	maxdepth:1.05,maxheight:1.05,strut,line,split
math:halfline	maxdepth:1.05,maxheight:1.05,strut,halfline,split
math:-line	maxdepth:1.05,maxheight:1.05,strut,-line,split
math:-halfline	maxdepth:1.05,maxheight:1.05,strut,-halfline,split
You can define y	our own variants building on top of an existing one:
\definegrids	napping[math:my][math,]
page boundaries	the effect of the split directive here. It triggers a check at the but you need to keep in mind that this is not always robust as themselves can be triggered by and inject anything.
	b
	$a = \frac{rac{b}{c}}{rac{d}{c}} (ext{top 1 default})$
	$\frac{d}{e}$
	$a = \frac{\frac{b}{c}}{\underline{d}}(\text{top 2 default})$
	$a = \frac{c}{d}(\text{top 2 default})$
	\overline{e}
	b
	$a = \frac{\frac{\sigma}{c}}{d}(\text{top 3 default})$
	$\frac{d}{e}$
	$\frac{b}{c}$
	$a = \frac{c}{\underline{d}}(\text{top 4 default})$
	e
	b
	$a = \frac{c}{\frac{d}{d}}(\text{top 5 default})$
	e
	b
	$a = \frac{\dot{c}}{d}(\text{top 6 default})$
	a = -(top 6 default)

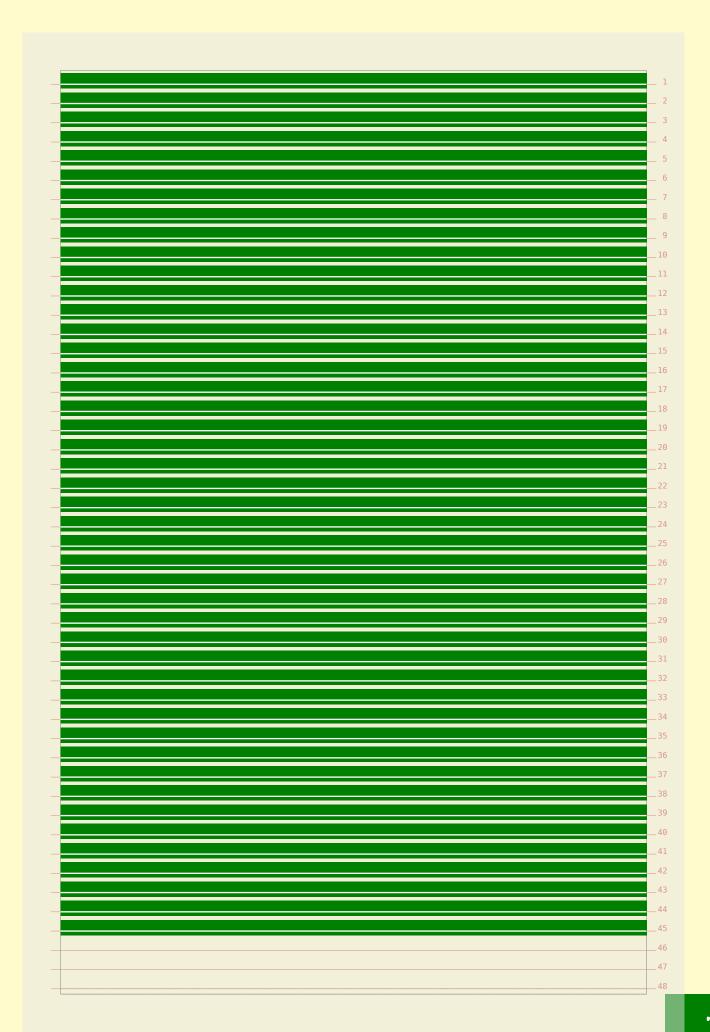

```
\frac{\overline{c}}{d}(top 10 compensated)
                                    (top 11 compensated)
                                  \frac{\overline{c}}{d}(top 12 compensated)
                                  \frac{c}{d}(top 13 compensated)
                                  \frac{\overline{c}}{d}(top 14 compensated)
                             a = \frac{\overline{c}}{d}(\text{top 15 compensated})
As said, the compensation is achieved with the page directive. The previous
pages were rendered using:
   \dorecurse {15} {
        \startformula[grid={math,-halfline}]
              a = \frac {\frac {b} {c}} {\frac {d} {e}}
              (\hbox{top #1 default})
         \stopformula
         \blank[samepage]
         \fakeline
and
                                                                                            45
   \dorecurse {15} {
         \startformula[grid={math,-halfline,split}]
```

Graphics, tables and alike are often treated as floating bodies. This means that when such a body does not fit on the current page, it will be moved to the next one. In the examples we will use figures, but everything we demonstrate here applies to all floats. A side float is a float which placement one way or another depends on the text that follows it. In its simplest form, the text flows around it, for instance in: \placefigure[left,none]{caption}{\framed[height=1cm]{graphic}} The first keyword of such a call is treated as a placement directive, so this figure will be placed left. The none directive nils the caption. graphic When the figure does not fit on the page, a page break is issued. A figure can span multiple paragraphs. When a next graphic is placed the previous figure will be padded if needed. First an example of multiple paragraphs. graphic Multiple floats in a row will lead to padding. The amount of padding is a combi-31 nation of empty lines and the normal white space following the float. The visual quality of the result depends on the graphic itself. graphic graphic Here we show the baseline of the first paragraph after the float as well as the 47 The whitespace around a graphic also depends on the inter-paragraph 48

[edgefigure] [figure] \setupfloat [edgefigure] [leftmargindistance=-\innercombitotal, default={left,none,low,high}] The \innercombitotal is one of the many available dimensions. This measure is the combined width of the margin and edge. \placeedgefigure {} {\framed[width=1.5cm]{!}} \placeedgefigure {} {\framed[width=\innercombitotal]{!}} You need to be aware of the fact that the margins and edges are not related to the backspace and cut space settings. When you set up a layout, you need to 26 think of the right page as starting point. In a double sided layout, the margins are swapped in the page composition stage. Unless you explicitly go to a left or right page, you don't know if your left margin will be swapped or not. For this reason ConT $_{\mathsf{F}}\mathsf{X}\mathsf{t}$ provides the inner and outer margin/edge dimensions. 30 These are automatically synchronized when the float is constructed. So, if you want to automatically adapt the float placement and width to the current left margin in a double sided document, you can use the inner dimensions. dimension left page right page \outermarginwidth \leftmarginwidth \rightmarginwidth \rightmarginwidth \leftmarginwidth \innermarginwidth \outermargindistance \leftmargindistance \rightmargindistance \innermargindistance \rightmargindistance \leftmargindistance Similar dimensions are available for the edges. You can save yourself some calcu- 41 lations by using the following dimensions: \leftmargintotal left margin width + left margin distance \rightmargintotal right margin width + right margin distance 45 \innermargintotal inner margin width + inner margin distance **\outermargintotal** outer margin width + outer margin distance 47

As a result of manipulating the floats margin settings, the side floats can start in the margin (or edge). You should not confuse this with margin floats, i.e. side floats that are explicitly placed in the margins. \placefigure[leftmargin,none] {} {\framed{!}} ! \placefigure[leftmargin,none] {} {\framed[width=.5cm]{!}} ! \placefigure[leftmargin,none] {} {\framed[width=1.5cm]{!}} \placefigure[leftmargin,none] {} {\framed[width=5cm]{!}} The margin side floats align to the margin and the edge floats to the edge. This way you can create bleeding figures. \placefigure[leftedge,none] {} {\framed{!}} There are situations where you don't know the dimensions in advance. In order to prevent unwanted side effects, for instance part of a graphic disappearing outside 43 the page boundary, ConTEXt provides a few options. The most crude one is setting the criterium, as in: \setupfloat [figure]

[criterium=.25\textwidth] This will automatically turn figures that are wider than 25% of the text width into normal floats instead of side floats. But let's not fall back on that feature now. You can use maxwidth and minwidth variables to control the placement in more detail. The exact result depends on the settings of location. By default we center, but you can set the location to left or right to achieve a different alignment. \definefloat [midmarginfigure] [figure] \setupfloat [midmarginfigure] [minwidth=\leftmarginwidth, default={leftmargin,none}] You can use maxwidth and minwidth variables to control the placement in more detail. The exact result depends on the settings of location. By default we center, 20 but you can set the location to left or right to achieve a different alignment. \placemidmarginfigure {} {\framed[width=1.5cm]{!}} The meaning of maxwidth depends on the kind of float. First we place a left float with a width smaller than maxwidth. \setupfloat[figure][maxwidth=2cm] \placefigure[left,none]{}{\framed[width=1cm]{!}} When the width exceeds the maxwidth, the float will be centered. This is because we have no reference alignment point. \placefigure[left,none]{}{\framed[width=5cm]{!}} ! In margin floats, the maxwidth settings have a different result. First we place a small graphic.

\setupfloat[figure] [maxwidth=\leftmarginwidth] A wider than maxwidth graphic will behave like a mixture of a margin and side float. Watch how we align the float to the margin. \placefigure[leftmargin,none]{}{\framed[width=5cm]{!}} ! Instead of setting the width you can give hanging a try. The next exademonstrate this. \placefigure[leftmargin,hanging,none]{}{\framed[width=5cm]{!}} ! \placefigure[leftmargin,hanging,none]{}{\framed[width=5cm]{!}} ! You can move down/up margin floats with the \movesidefloat macro. shifts come in handy when you have multiple side floats near to each other.	\setupfloat[figure] [maxwidth=\leftmarginwidth] A wider than maxwidth graphic will behave like a mixture of a margin and side float. Watch how we align the float to the margin. \placefigure[leftmargin,none]{}{\framed[width=5cm]{!}} ! Instead of setting the width you can give hanging a try. The next exam demonstrate this. \placefigure[leftmargin,hanging,none]{}{\framed[width=5cm]{!}} !
differ—we don't need to use inner and outer dimensions. \setupfloat[figure] [maxwidth=\leftmarginwidth] A wider than maxwidth graphic will behave like a mixture of a margin and side float. ```
In this chapter we will discuss a few more tricks to control float placement. This
control is needed if you want to typeset documents in a semi desk top publishing
When you combine technical graphics, you may wish to align the content optically. 6
This can be done with the offset command. We will demonstrate this with a
couple of MetaPost graphics:
   \startreusableMPgraphic{alpha}
     fill fullsquare xyscaled( 2cm, 2cm) withcolor \MPcolor{red};
     fill unitsquare xyscaled(+.5cm,+.5cm) withcolor \MPcolor{gray};
   \stopreusableMPgraphic
  \startreusableMPgraphic{beta}
     fill fullsquare xyscaled( 2cm, 2cm) withcolor \MPcolor{red};
     fill unitsquare xyscaled(+.5cm,-.5cm) withcolor \MPcolor{gray};
  \stopreusableMPgraphic
   \startreusableMPgraphic{gamma}
     fill fullsquare xyscaled( 2cm, 2cm) withcolor \MPcolor{red};
     fill unitsquare xyscaled(-.5cm,-.5cm) withcolor \MPcolor{gray};
  \stopreusableMPgraphic
  \startuseMPgraphic{delta}
     fill fullsquare xyscaled( 2cm, 2cm) withcolor \MPcolor{red};
     fill unitsquare xyscaled(-.5cm,+.5cm) withcolor \MPcolor{gray};
   \stopuseMPgraphic
   \startcombination[2*2]
     {\reuseMPgraphic{alpha}} {alpha}
     {\reuseMPgraphic {beta}} {beta}
     {\reuseMPgraphic{gamma}} {gamma}
     {\reuseMPgraphic{delta}} {delta}
   \stopcombination
In figure 6.1 we place these graphics in a 2*2 grid. As you can see, the centers
don't align well.
In figure 6.2 the centers of the graphic align well. This is accomplished by adding
some space around the graphics.
   \startcombination[2*2]
     {\offset[rightoffset=1cm] {\reuseMPgraphic{alpha}}} {alpha}
     {\offset[bottomoffset=.5cm]{\reuseMPgraphic {beta}}} {beta}
     {\offset[bottomoffset=.5cm]{\reuseMPgraphic{gamma}}} {gamma}
                                                                          45
     {\offset[leftoffset=1cm] {\reuseMPgraphic{delta}}} {delta}
   \stopcombination
                                                                          47
```

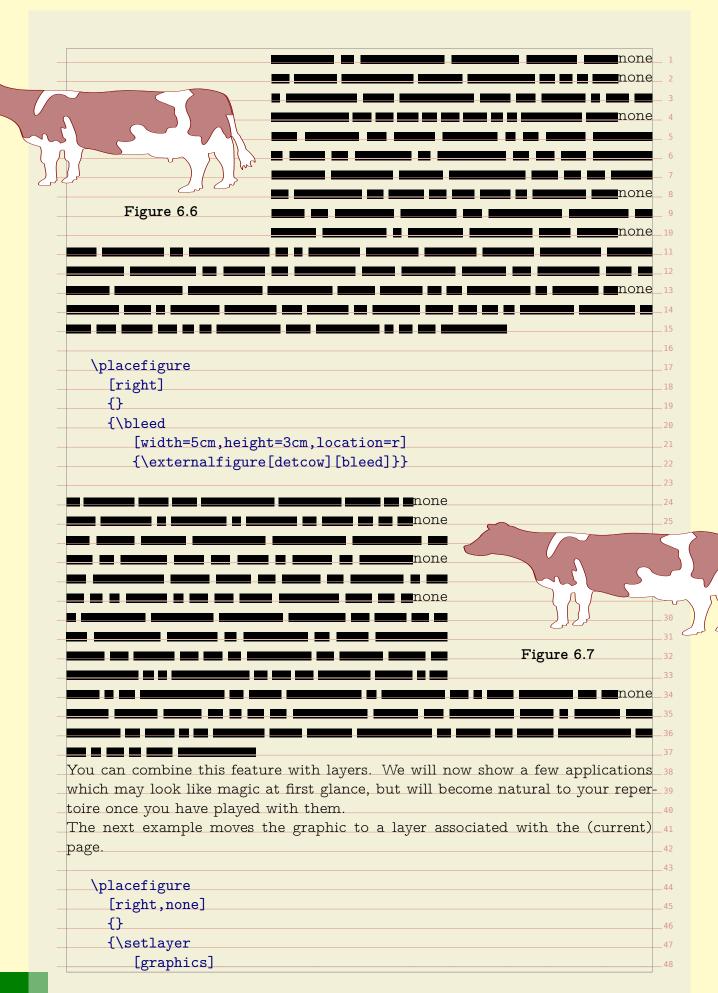

Method 0 just looks at the raw dimensions, while method 1 lessens the maximum text height by one percent, thereby playing safe. Method 2 takes a window of 1 point. This may lead to better decisions since we may run into rounding errors of several scaled points (which is small but troublesome). Method 2 is well suited when typesetting on a grid, because there everything has to fit in a rounded number of lines, which leaves no room for rounding errors. grid mode	by security till	calculation method. You can set the methods as follows:
text height by one percent, thereby playing safe. Method 2 takes a window of a point. This may lead to better decisions since we may run into rounding errors of several scaled points (which is small but troublesome). Method 2 is well suited when typesetting on a grid, because there everything has to fit in a rounded number of lines, which leaves no room for rounding errors. Grid mode yes no sidemethod 2 1 textmethod 2 0 As you may know by now, we can use the directives high, low, height, depth and line to influence the spacing around a side float. A real tight spacing can be achieved with fit. \[\text{placefigure}[left,fit,none]{}{some graphic} \] This kind of placements only make sense in special situations because normally you don't want the graphic to touch the text. If you think that this is all a user may want, you're wrong. It is not imaginary that graphics have small pieces sticking out and/or lots of white space as part of their design. In that case, the bounding box can be set to a smaller size. Now, when handling a side float, ConTEXt first places the float and then starts with typesetting the paragraph, cleverly avoiding the graphic. However, when the graphic is virtually larger than its known size, it may cover part of the preceding paragraph. How come that the graphic starting this paragraph does not do that? It is because we explicitly moved it to the background. This involves some preparation. At the document level, we define a layer called graphic. \[\text{\text{definelayer}[graphics] [position=yes]} \] The position directive tells ConTEXt that it should honour the position of the graphic. Next we must make sure that this layer is placed. \[\text{\text{\text{setupbackgounds}[page] [background=graphics]} \]	\setupflo	ats[textmethod=0,sidemethod=1]

default={left,	none}]
nstead of resetting the	side spacing, we could have default to high, low, but this
9	ne default placement and still get zero spacing.
Throughout this manua	al we discuss features related to overlays and layers. These
	ntent around in ways that either or not depend on the text
	ne to another trick based on these mechanisms: bleeding.
	nent, you need to take into account that when graphics go
	dary, you need to compensate for inaccuracies in cutting
	cs are called bleeding graphics and the amount of bleed is
often a few millimeters	e such graphics is to use the correct dimensions and play
· ·	e such graphics is to use the correct dimensions and play and distances in combination with backspace and cut space
•	out and by using a well designed set of predefined graphic
	andle this quite well. A bleeding figure can be defined as
follows:	1 0 0
\definefloat	
[edgefigure]	
[figure]	
[IIgure]	

[edgefigure] [default={inner,height,high,low,none}, maxwidth=4cm] \defineexternalfigure [edgefigure] [width=\dimexpr\backspace+4cm-1mm\relax, lines=4] The default placement is pre-configured to have no additional vertical space and align on the height of a line (this is default behaviour so the height key is redun- 11 dant here. The 1mm in the previous definition simulates what happens when a page is cut off slightly wrong: we get an annoying gap. \placeedgefigure {\externalfigure[hacker][edgefigure]} One of the nice things about TEX is that you can fine tune dimensions pretty well. So, instead of the previous placement, which turns out rather ugly, we can come up with a better one: \setupfloat [edgefigure] [default={inner,height,high,low,none}, maxwidth=4cm, margin=\strutdepth] \defineexternalfigure [edgefigure] [width=\dimexpr\backspace+4cm+2mm\relax, height=\dimexpr3\lineheight+\strutheight\relax] This time we take no risk and add 2mm to the dimensions so that we can be sure that the edge of the graphic falls outside the page boundary. The ConTEXt resourse library modules provide means to report back the dimen- 47 sions of graphics used in a document, so that you can develop (tune) them with 48

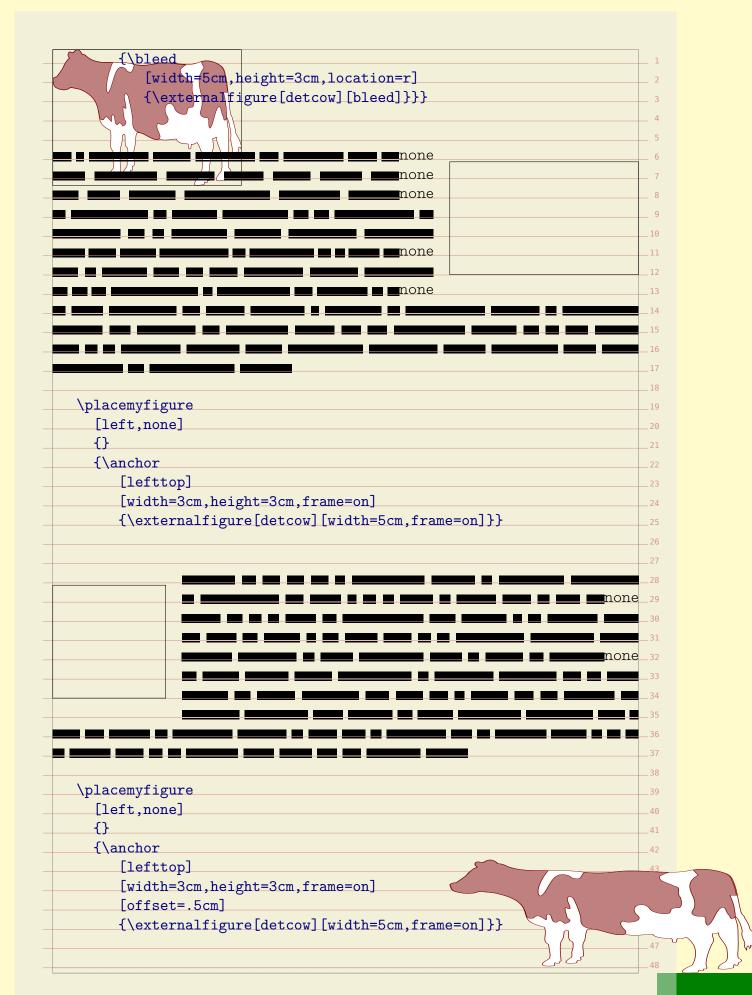

```
the proper dimensions. In practice a slightly wider than normal graphic (scaling
it horizontally a few millimeters more) does not harm the visual appearance that
much, so adapting a graphic to this kind of bleeding is not really needed.
In addition to this (rather natural) way of adding bleed to a graphic, you can
apply the \bleed macro. In the previously discussed method the figure placement
mechanisms work with the real dimensions. The bleed macro is using scaling in
a different way: from the perspective of ConTFXt the graphic remains its original
dimensions and the figure placement mechanisms will act accordingly. We will
give a couple of examples of using this macro.
Permitted bleeding locations are 1, r, t, b, 1r, b1, br, t1 and tr.
   \placesomefloat
     [left, none, fit]
     {}
     {\setupbleeding[offset=5mm]%
      \bleed[width=5cm,height=1cm,location=1]
        {\externalfigure[mill][bleed]}}
   \placesomefloat
     [left, none, fit]
     {}
     {\setupbleeding[offset=2mm]%
      \bleed[width=5cm,height=1cm,location=1]
         {\externalfigure[mill][bleed]}}
The amount of bleeding depends on the postprocessing. In the previous paragraph
we used a bleed offset of 5mm, and here we used 2mm. Because the graphic is _{	ext{40}}
scaled in order to match the bleed, it will be slightly distorted. With small values
this will go unnoticed. You can set the offset with:
   \setupbleeding[offset=5mm]
Bleeding itself is accomplished by the \bleed macro as in:
   \bleed
```

```
[width=5cm,height=1cm,location=1]
     {\externalfigure[mill][width=\bleedwidth,height=\bleedheight]}
It is kind of awkward to pass those two dimensions so here is a shorter way of
doing the same:
   \bleed
     [width=5cm,height=1cm,location=1]
     {\externalfigure[mill][bleed]}
In fact, this uses the following definition:
   \defineexternalfigure[bleed][width=\bleedwidth,height=\bleedheight]
You can influence the scaling of a graphic by setting the {	t stretch} parameters. 15
The location parameter determines the direction of the stretch: 1 (left), r (right), 16
t (top), b (bottom) or a combination of these. We will now combine the previous
example code with this knowledge.
   \placefigure
     [left]
     {}
     {\bleed
        [stretch=no,voffset=0pt,hoffset=1cm]
        {\externalfigure[detcow][bleed]}}
  Figure 6.5
   \placefigure
     [left]
     {}
     {\bleed
        [width=5cm,height=3cm,location=1]
        {\externalfigure[detcow][bleed]}}
                                                                              47
```

The background mechanisms present in ConTFXt have evolved over time and with computers becoming faster, you can expect new functionality to show up and existing functionality to start using this technology. A simple background consist of a colored area. Many commands accept settings like: ...[background=color,backgroundcolor=red,backgroundoffset=3pt] Instead of such an area you can define one or more so called overlays: \defineoverlay[one][...] \defineoverlay[two][...] ...[background={one,two}] The name overlay comes from the fact that you stack them on top of each other. 17 A special overlay is foreground, and deep down in ConT_FXt there are more 18 predefined overlays. In the MetaFun manual you will find example of usage, so here we stick to a simple code snippet for testing this functionality: \defineoverlay[one][\green A] \defineoverlay[two][\red \framed[background=one] {1} \framed[background={one,two}] {1---2} The rather ugly result is: 1-18-2 You can construct overlays by using TEX boxing primitives or commands like 32 framed. Alternatively you can use another mechanism: layers. Layers collect 33 content and flush that when asked, for instance when an overlay is constructed. $^{ ext{ iny 34}}$ Layers can be independent of a page, or bound to a specific page number, left or 35 right hand pages. Here we look at independent layers. All these mechanisms are fine tuned for cooperating with the output routine (the 37 part of $ext{T}_{ ext{E}} ext{X}$ that deals with composing pages) and are well interact quite well $ext{38}$ with MetaPost graphics. Details of usage and tricks are revealed in this manual 39 as well as in styles that come with ConT $_{
m F}$ Xt. In this chapter we will apply layers $_{ ext{40}}$ to graphics. For this we need a few setups, like: \setupbackgrounds [page] [background=pagegraphics] Here we have set up the page background to use an overlay called pagegraphics. 47 However, instead of an overlay, we will use a layer. This layer will collect content 48

that goes into the page background. Whenever a layer is defined, an overlay is automatically defined as well. \definelayer [pagegraphics] [x=-2mm,y=-2mm, width=\paperwidth, height=\paperheight] When you fill a layer with content, you can influence the placement with the ${f x}$ and y parameters as well as hoffset and voffset, whichever you prefer. The 12 reference point and alignment are set with corner and location. Live can be made easier by using presets, especially for our intended usage. The 14 following presets are predefined. \definelayerpreset [corner={left,top}, location={right,bottom}] [lefttop] \definelayerpreset [righttop] [corner={right,top}, location={left,bottom}] \definelayerpreset [leftbottom] [corner={left,bottom}, location={right,top}] \definelayerpreset [rightbottom] [corner={right,bottom},location={left,top}] Because for this layer we have also preset the x and y, those corners are laying a 26 few millimeters outside the page area. We have preset the size as well, otherwise 27 all corners would end up in the top left corner. We will now fill this layer. Because the layer is hooked into the page, it will be flushed when the page is constructed. After the page is written to the output file, 30 the layer is emptied, unless its state is set to repeat. \setlayer [extras] [preset=lefttop] {\externalfigure[hacker]} \setlayer [extras] [preset=righttop] {\externalfigure[hacker]} \setlayer [extras] [preset=leftbottom] {\externalfigure[hacker]} \setlayer [extras] [preset=rightbottom] {\externalfigure[hacker]} Once you got the picture of layering, you will start using this mechanism for all $_{ exttt{38}}$ kind of tasks. Instead of putting layers in a background, you can also directly place them, by using one of the two (equivalent) commands: \composedlayer{identifier} \placelayer[identifier]

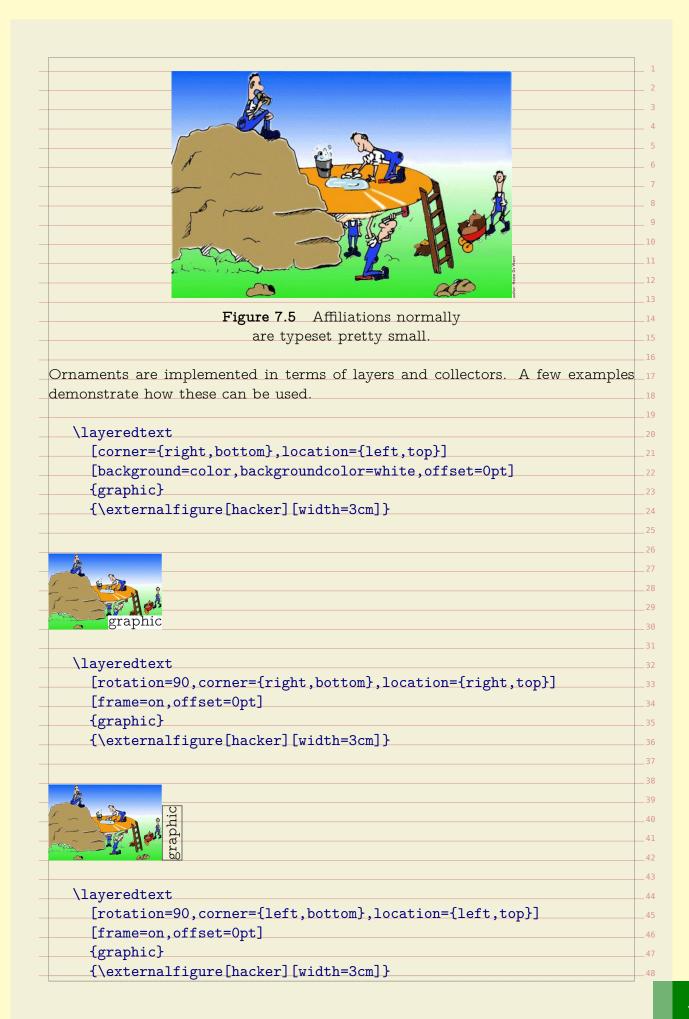

Layer are quite convenient for defining title pages, colophons, and special section

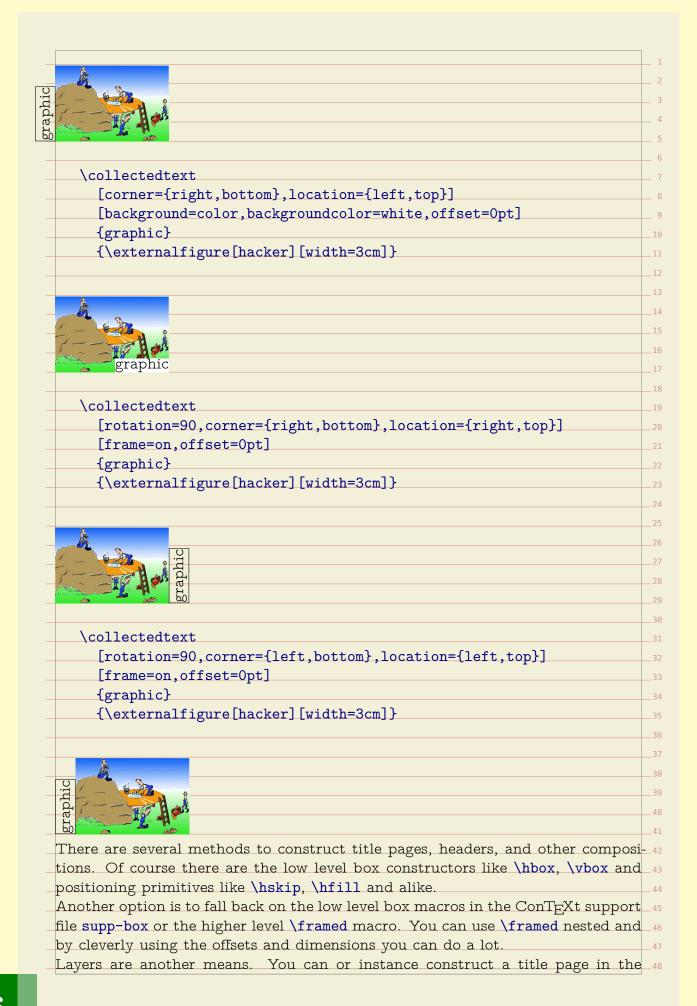

On top of the layer mechanism we have build a few more mechanisms, like ornaments. You can use ornaments to annotate graphics in such a way that the

heads, especially in combination with \framed.

[chapter]
     [header]
     [\setups{chapter}]
The setups are just series of typesetting instructions. For the sake of readability,
we have split them up.
  \startsetups chapter
     \setups[chapter:title]
     \setups[chapter:number]
     \setups[chapter:finish]
  \stopsetups
The setups will use a dedicated layer for the chapter title:
  \definelayer
     [chapter]
     [width=\dimexpr\makeupwidth+\cutspace\relax,
      height=\headerheight]
The following code uses a macro \setlayerframed. This is a combination between
\setlayer and \framed. We use two placement macros to typeset the title and
number. When doing so, we need to take care of both numbered chapters and
unnumbered titles.
  \startsetups chapter:title
     \setlayerframed
       [chapter]
       [x=\dimexpr\makeupwidth+\cutspace\relax,location={left,bottom}]
       [height=\headerheight,
        foregroundcolor=white,
        background=color,
        backgroundcolor=blue,
        frame=off,
        offset=none,
        align={right,lohi}]
       {\hbox spread .5\cutspace
          {\hss}
                                                                            40
           \doiftextelse{\placeheadtext[chapter]}%
             {\placeheadtext[chapter]}%
             {\placeheadtext[title]}%
           \hss}\space
        \vskip.5cm}
                                                                            45
  \stopsetups
```

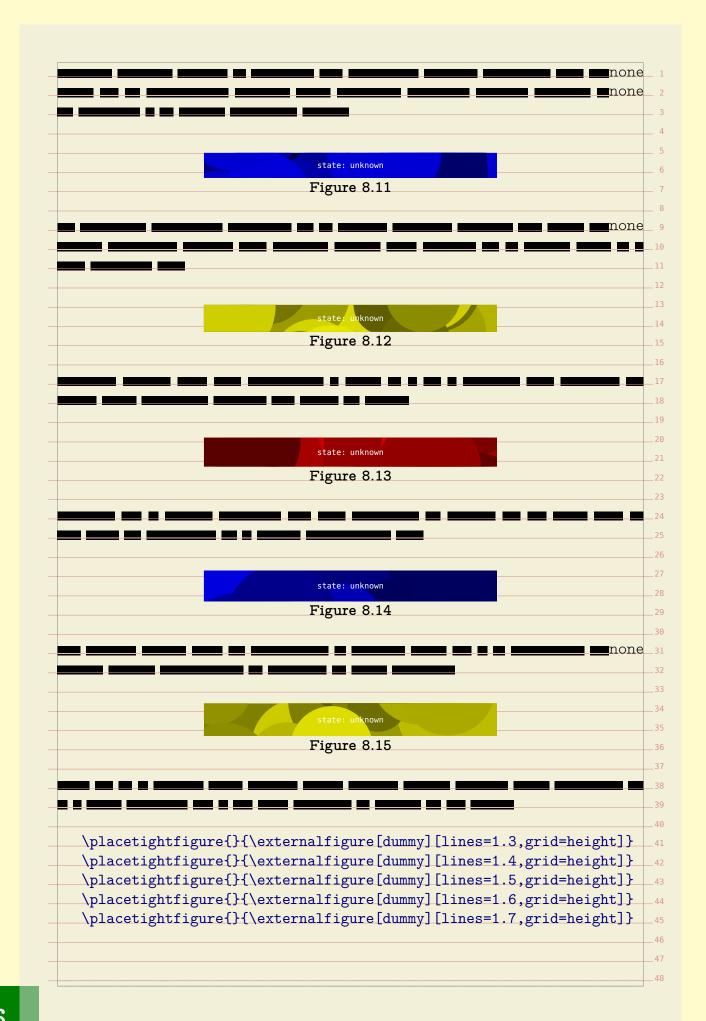

```
Definitions like these may look complicated but in practice you will construct
them piece-wise.
   \startsetups chapter:number
     \setlayerframed
        [chapter]
        [x=\dimexpr\makeupwidth+\cutspace\relax,
        y=\vsize,
        location={left,bottom}]
        [width=\dimexpr\cutspace-\rightmargindistance\relax,
        height=\dimexpr\cutspace-\rightmargindistance\relax,
        foregroundcolor=white,
        background=color,
        backgroundcolor=red,
        frame=off,
         offset=none,
        align={middle,lohi}]
        {\hbox to \hsize
           {\hskip.5cm\hss
            \doifmode{*bodypart}{\placeheadnumber[chapter]}%
   \stopsetups
The finishing touch is just a dummy frame with the chapter background. We
could have used the header text background instead.
   \startsetups chapter:finish
     \framed
        [width=\makeupwidth,
        height=\headerheight,
        background=chapter,
        frame=off]
       {}
   \stopsetups
As the title of this manual suggests: it's in the details. Most of our time is spent in 40
optimizing spacing issues. If you're designing the layout yourself, for a large part 41
you can fall back on the consistent spacing provided by 	ext{T}_{	ext{F}}	ext{X}, i.e. think in terms 	ext{	iny 42}
of em's, ex's and fractions or multiples of \bodyfontsize, as well as base you're 43
dimensions on those provided by the layout. When dealing with translating a dtp
layout into something T_{
m E}X, definitions like the above will often look more messy. 45
                                                                                47
```

		1 2
	In this manual we pay quite some words on ways to snap your content on a grid	
	When dealing with grids, we often run into conflicting situations where we have	
	to make the best of it. Let's again deal with an aspect of graphics.	
	One of the strong points of T_{EX} is that it can deal with graphics automatically	7, •
_	which means that you seldom have to tweak dimensions or placements unless	_ 7
	you're dealing with grids. In that case you need to make sure that the height of	
	graphics consistently match the height of lines (or multiples of lines). It is for	_ 9
	this purpose that the graphic inclusion macro has a grid entry.	1
_	We will illustrate its usage using a dedicated figure class where we have set the	1:
	space between figure and caption to zero.	12
_		13
	\definefloat[tightfigure][tightfigures][figure]	14
_	\setupcaption[tightfigure][inbetween=]	15
		16
	The grid parameter controls rounding of the height of a graphic in the following	17
	way:	18
		19
	yes safe rounding to an equal number of lines	2(
_	fit tight rounding to an equal number of lines	2:
	height same as yes but incremented by linedepth	22
		23
	On the next pages we demonstrate the effects of these settings. At the bottom	<u>2</u>
	of a page we show the placement commands. On the last pages we've hidden the	2.5
	captions with:	26
		27
	\setupfloat[tightfigure][default={here,none}]	28
		29
	As you will notice, the height option is handy when the caption is positioned	L 30
	directly under the graphic.	3:

About this document

	<u> </u>
	_ :
s document is typeset in ConTEXt using LuaTEX with MetaPost. We use only	
font: the Computer Modern Typewriter. The verbatim portions of the tex	
typeset in its mono spaced variant. One of the reasons that I chose this font is	
t we need a mono spaced font to typeset the example code, and the Compute:	
dern Typewriter is one the best there is. This font combines well with many	
er typefaces, but the sometimes excessive use of different fonts (and sizes) in	
styles that I have to implement made me long for simplicity. And so I decided	
tick to one font. A careful reader will notice that this document has character	
truding enabled (resulting in hanging punctuation).	1
use a couple of colors. Again, I went for simplicity and use rather primary	
ors, although I do use them in transparent variants as well.	1
ere is not much more to say, apart from that I want to thank our customers	
well as $ ext{ConT}_{ ext{E}} ext{X} ext{t}$ users for asking me to implement dtp competing styles and	
tures. Their demands drive $ConT_{\hbox{\scriptsize E}}Xt$ in directions we could not have foreseen	1
en we started its development.	_1
use a (transparent) gray background behind the text so that we have ar	L 18
ication where the text area is positioned relative to the page. It also enables	19
to comfortably turn on the grid.	2(
ne features shown here are relatively new and therefore they occasionally are	2:
proved. As a result some aspects of their functionality may change.	2;
